

4GHz Ultra-Low Bias Current FET Input Op Amp

FEATURES

- Gain Bandwidth Product: 4GHz
- Low Input Bias Current:
 - $\pm 3\text{fA}$ Typ. Room Temperature
 - 4pA Max at 125°C
- Current Noise (100kHz): $7\text{fA}/\sqrt{\text{Hz}}$
- Voltage Noise (1MHz): $4.0\text{nV}/\sqrt{\text{Hz}}$
- Extremely Low C_{IN} 0.45pF
- Rail-to-Rail Output
- $A_V \geq 10$
- Slew Rate: $+1500\text{V}/\mu\text{s}$, $-1000\text{V}/\mu\text{s}$
- Supply Range: 3.1V to 5.25V
- Quiescent Current: 16.5mA
- Operating Temp Range: -40°C to 125°C
- Single in 8-Lead SO-8, 6-Lead TSOT-23 Packages
- Dual in 8-Lead MS8, 3mm \times 3mm 10-Lead DFN 10 Packages

APPLICATIONS

- Transimpedance Amplifiers
- ADC Drivers
- Photomultiplier Tube Post-Amplifier
- Low I_{BIAS} Circuits

DESCRIPTION

The [LTC®6268-10/LTC6269-10](#) is a single/dual 4GHz FET-input operational amplifier with extremely low input bias current and low input capacitance. It also features low input-referred current noise and voltage noise making it an ideal choice for high speed transimpedance amplifiers, and high-impedance sensor amplifiers. It is a decompensated op amp that is gain-of-10 stable.

It operates on 3.1V to 5.25V supply and consumes 16.5mA per amplifier. A shutdown feature can be used to lower power consumption when the amplifier is not in use.

The LTC6268-10 single op amp is available in 8-lead SOIC and 6-lead SOT-23 packages. The SOIC package includes two unconnected pins which can be used to create an input pin guard ring to protect against board leakage currents. The LTC6269-10 dual op amp is available in 8-lead MSOP with exposed pad and 3mm \times 3mm 10-lead DFN packages. They are fully specified over the -40°C to 85°C and the -40°C to 125°C temperature ranges.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The inputs are protected by two series connected ESD protection diodes to each power supply. The input current should be limited to less than 1mA. The input voltage should not exceed 200mV beyond the power supply.

Note 3: A heat sink may be required to keep the junction temperature below the absolute maximum rating when the output is shorted indefinitely.

Note 4: The LTC6268-10I/LTC6269-10I is guaranteed to meet specified performance from -40°C to 85°C . The LTC6268-10H/LTC6269-10H is guaranteed to meet specified performance from -40°C to 125°C .

Note 5: Thermal resistance varies with the amount of PC board metal connected to the package. The specified values are for short traces connected to the leads.

Note 6: The input bias current is the average of the currents into the positive and negative input pins. Typical measurement is for S8 package.

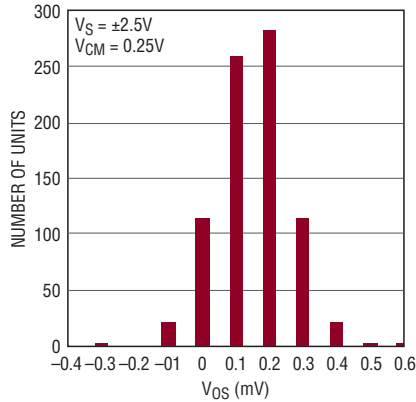

Note 7: Full Power Bandwidth is determined from distortion performance in a gain-of-10 configuration with $\text{HD2/HD3} < -40\text{dB}$ (1%) as the criteria for a valid output.

Note 8: This parameter is specified by design and/or characterization and is not tested in production.

Note 9: The LTC6268-10/LTC6269-10 is capable of producing peak output currents in excess of 135mA. Current density limitations within the IC require the continuous current supplied by the output (sourcing or sinking) over the operating lifetime of the part be limited to under 135mA (Absolute Maximum).

PIN FUNCTIONS

-IN: Inverting Input of the Amplifier. The voltage range of this pin is from V^- to $V^+ - 0.5\text{V}$.

+IN: Non-Inverting Input. The voltage range of this pin is from V^- to $V^+ - 0.5\text{V}$.

V^+ : Positive Power Supply. Total supply ($V^+ - V^-$) voltage is from 3.1V to 5.25V. Split supplies are possible as long as the total voltage between V^+ and V^- is between 3.1V and 5.25V. A bypass capacitor of $0.1\mu\text{F}$ should be used between V^+ to ground as close to the pin as possible.

V^- : Negative Power Supply. Normally tied to ground, it can also be tied to a voltage other than ground as long

as the voltage difference between V^+ and V^- is between 3.1V and 5.25V. If it is not connected to ground, bypass it to ground with a capacitor of $0.1\mu\text{F}$ as close to the pin as possible.

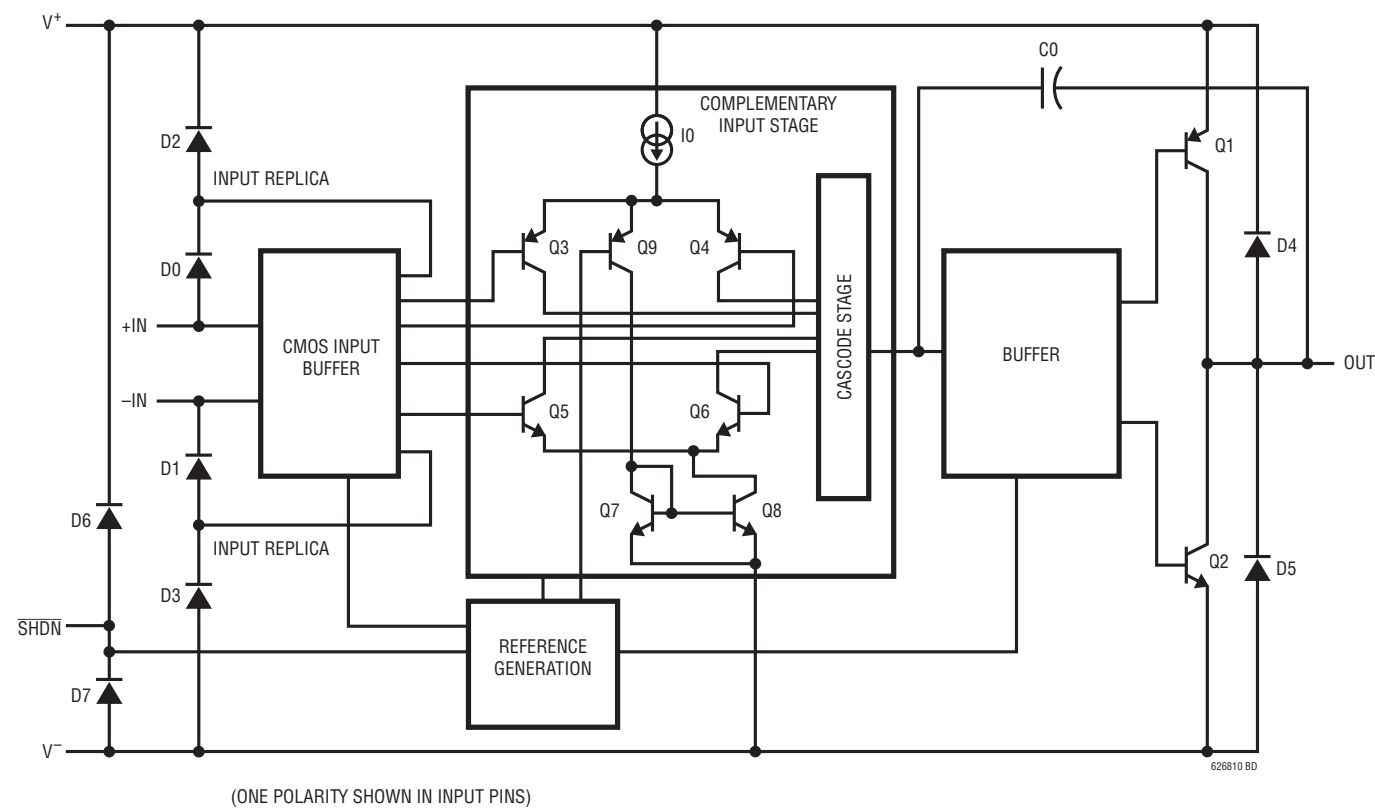

$\overline{\text{SHDN}}$, $\overline{\text{SDA}}$, $\overline{\text{SDB}}$: Active Low op amp shutdown, threshold is 0.75V above the negative supply, V^- . If left unconnected, the amplifier is enabled.

OUT: Amplifier Output.

NC: Not connected. May be used to create a guard ring around the input to guard against board leakage currents. See Applications Information section for more details.

SIMPLIFIED SCHEMATIC

LTC6268-10 Simplified Schematic Diagram

OPERATION

The LTC6268-10/LTC6269-10 input signal range is specified from the negative supply to 0.5V below the positive power supply, while the output can swing from rail-to-rail. The schematic above depicts a simplified schematic of the amplifier.

The input pins drive a CMOS buffer stage. The CMOS buffer stage creates replicas of the input voltages to boot strap the protection diodes. In turn, the buffer stage drives a complementary input stage consisting of two differential

amplifiers, active over different ranges of input common mode voltage. The main differential amplifier is active with input common mode voltages from the negative power supply to approximately 1.55V below the positive supply, with the second amplifier active over the remaining range to 0.5V below the positive supply rail. The buffer and output bias stage uses a special compensation technique ensuring stability of the op amp. The common emitter topology of output transistors Q1/Q2 enables the output to swing from rail-to-rail.

APPLICATIONS INFORMATION

Noise

To minimize the LTC6268-10's noise over a broad range of applications, careful consideration has been placed on input referred voltage noise (e_N), input referred current noise (i_N) and input capacitance C_{IN} .

For a transimpedance amplifier (TIA) application such as shown in Figure 1, all three of these op amp parameters, plus the value of feedback resistance R_F , contribute to noise behavior in different ways, and external components and traces will add to C_{IN} . It is important to understand the impact of each parameter independently. Input referred

voltage noise (e_N) consists of flicker noise (or 1/f noise), which dominates at lower frequencies, and thermal noise which dominates at higher frequencies. For LTC6268-10, the 1/f corner, or transition between 1/f and thermal noise, is at 40kHz. The i_N and R_F contributions to input referred noise current at the minus input are relatively straight forward, while the e_N contribution is amplified by the noise gain. Because there is no gain resistor, the noise gain is calculated using feedback resistor (R_F) in conjunction with impedance of C_{IN} as $(1 + 2\pi R_F \cdot C_{IN} \cdot \text{Freq})$, which increases with frequency. All of the contributions will be limited by the closed loop bandwidth. The equivalent input current noise is shown in Figure 2 and Figure 3, where e_N represents contribution from input referred voltage noise (e_N), i_N represents contribution from input referred current noise (i_N), and R_F represents contribution from feedback resistor (R_F). TIA gain (R_F) and capacitance at input (C_{IN}) are also shown on each figure. Comparing Figure 2 and Figure 3, i_N dominates at higher frequencies. At lower frequencies, the R_F contribution dominates. Since average wide band e_N is $4.0\text{nV}/\sqrt{\text{Hz}}$ (see typical performance characteristics), R_F contribution will become a lesser factor at lower frequencies if R_F is less than 860Ω as indicated by the following equation:

$$\frac{e_N/R_F}{\sqrt{4kT/R_F}} \geq 1$$

Figure 1. Simplified TIA Schematic

APPLICATIONS INFORMATION

Figure 2

Figure 3

Optimizing the Bandwidth for TIA Application

The capacitance at the inverting input node can cause amplifier stability problems if left unchecked. When the feedback around the op amp is resistive (R_F), a pole will be created with $R_F || C_{IN}$. This pole can create excessive phase shift and possibly oscillation. Referring to Figure 1, the response at the output is:

$$\frac{R_F}{1 + \frac{2\zeta s}{\omega} + \frac{s^2}{\omega^2}}$$

Where R_F is the DC gain of the TIA, ω is the natural frequency of the closed loop, which can be expressed as:

$$\omega = \sqrt{\frac{2\pi\text{GBW}}{R_F(C_{IN} + C_F)}}$$

Hence the maximum achievable bandwidth of TIA is:

$$f_{TIA} \text{ (Hz)} = \sqrt{\frac{\text{GBW}}{2\pi R_F(C_{IN})}}$$

ζ is the damping factor of the loop, which can be expressed as:

$$\zeta = \frac{1}{2} \left(\sqrt{\frac{1}{2\pi\text{GBW} \cdot R_F(C_{IN} + C_F)}} + R_F \left(C_F + \frac{C_{IN} + C_F}{1 + A_O} \right) \cdot \sqrt{\frac{2\pi\text{GBW}}{R_F(C_{IN} + C_F)}} \right)$$

Where C_{IN} is the total capacitance at the inverting input node of the op amp, GBW is the gain bandwidth of the op amp, and A_O is the DC open loop gain of the op amp.

The small capacitor C_F in parallel with R_F can introduce enough damping to stabilize the loop. By assuming $C_{IN} \gg C_F$, the following condition needs to be met for C_F ,

$$C_F > \sqrt{\frac{C_{IN}}{\pi \cdot \text{GBW} \cdot R_F}}$$

Since LTC6268-10 is a decompensated op amp with gain-of-10 stable, it requires that $C_{IN}/C_F \geq 10$. Table 1 shows the minimum and maximum C_F for R_F of 20k and 402k and C_{IN} of 1pF and 5pF.

Table 1. Min/Max C_F

R_F	$C_{IN} = 1\text{pF}$	$C_{IN} = 5\text{pF}$
20k Ω	60fF/100fF	140fF/500fF
402k Ω	13fF/100fF	31fF/500fF

APPLICATIONS INFORMATION

Achieving Higher Bandwidth with Higher Gain TIAs

Good layout practices are essential to achieving best results from a TIA circuit. The following two examples show drastically different results from an LTC6268-10 in a 402k TIA. (See Figure 4.) The first example is with an 0805 resistor in a basic circuit layout. In a simple layout, without expending a lot of effort to reduce feedback capacitance, the rise time achieved is about 87ns (Figure 5), implying a bandwidth of 4MHz ($BW = 0.35/t_r$). In this case, the bandwidth of the TIA is limited not by the GBW of the LTC6268-10, but rather by the fact that the feedback capacitance is reducing the actual feedback impedance (the TIA gain itself) of the TIA. Basically, it's a resistor bandwidth limitation. The impedance of the 402k Ω is being reduced by its own parasitic capacitance at high frequency. From the 4MHz bandwidth and the 402k low frequency gain, we can estimate the total feedback capacitance as $C = 1/(2\pi \cdot 4\text{MHz} \cdot 402\text{k}\Omega) = 0.1\text{pF}$. That's fairly low, but it can be reduced further.

With some extra layout techniques to reduce feedback capacitance, the bandwidth can be increased. Note that

Figure 4. LTC6268-10 and Low Capacitance Photodiode in a 402k Ω TIA

we are increasing the effective “bandwidth” of the 402k resistance. A very powerful method to reduce feedback capacitance is to shield the E field paths that give rise to the capacitance. In this particular case, the method is to place a ground trace between the resistor pads. Such a ground trace shields the output field from getting to the summing node end of the resistor and effectively shunts the field to ground instead. The trace increases the output load capacitance very slightly. See Figure 6 for a pictorial representation.

Figure 7 shows the dramatic increase in bandwidth simply by careful attention to low capacitance methods around the feedback resistance. Bandwidth and rise time went from 4MHz (87ns) to 34MHz (10.3ns), a factor of 8. The ground trace used for LTC6268-10 was much wider than that used in the case of the LTC6268 (see LTC6268 data sheet), extending under the entire resistor dielectric. Assuming all the bandwidth limit is due to feedback capacitance (which isn't fair), we can calculate an upper limit of $C_f = 1/(2\pi \cdot 402\text{k}\Omega \cdot 34\text{MHz}) = 11.6\text{fF}$.

Figure 5. Time Domain Response of 402k Ω TIA without Extra Effort to Reduce Feedback Capacitance. Rise Time Is 87ns and BW Is 4MHz

APPLICATIONS INFORMATION

Figure 6. A Normal Layout at Left and a Field-Shunting Layout at Right. Simply Adding a Ground Trace Under the Feedback Resistor Does Much to Shunt Field Away from the Feedback Side and Dumps It to Ground. Note That the Dielectric Constant of Fr4 and Ceramic Is Typically 4, so Most of the Capacitance Is in the Solids and Not Through the Air. Feedback C is Reduced from 100fF at Left to 11.6fF at Right

Maintaining Ultralow Input Bias Current

Leakage currents into high impedance signal nodes can easily degrade measurement accuracy of fA signals. High temperature applications are especially susceptible to these issues. For humid environments, surface coating may be necessary to provide a moisture barrier.

There are several factors to consider in a low input bias current circuit. At the femtoamp level, leakage sources can come from unexpected sources including adjacent signals on the PCB, both on the same layer and from internal layers, any form of contamination on the board from the assembly process or the environment, other components on the signal path and even the plastic of the device package. Care taken in the design of the system can mitigate these sources and achieve excellent performance.

Figure 7. LTC6268-10 in a 402kΩ TIA with Extra Layout Effort to Reduce Feedback Capacitance Achieves 10.3ns Total System Rise Time, or 34MHz Total System Bandwidth

The choice of device package should be considered because although each has the same die internally, the pin spacing and adjacent signals influence the input bias current. The LTC6268-10/LTC6269-10 is available in SOIC, MSOP, DFN and SOT-23 packages. Of these, the SOIC has been designed as the best choice for low input bias current. It has the largest lead spacing which increases the impedance of the package plastic and the pinout is such that the two input pins are isolated on the far side of the package from the other signals. The gull-wing leads on this package also allow for better cleaning of the PCB and reduced contamination-induced leakage. The other packages have advantages in size and pin count but do so by reducing the input isolation. Leadless packages such as the DFN offer the minimum size but have the smallest pin spacing and may trap contaminants under the package.

The material used in the construction of the PCB can sometimes influence the leakage characteristics of the design. Exotic materials such as Teflon can be used to improve leakage performance in specific cases but they are generally not necessary if some basic rules are applied in the design of conventional FR4 PCBs. It is important to keep the high impedance signal path as short as possible on the board. A node with high impedance is susceptible to picking up any stray signals in the system so keeping it as short as possible reduces this effect. In some cases, it may be necessary to have a metallic shield over this portion of the circuit. However, metallic shielding increases capacitance. Another technique for avoiding leakage paths is to cut slots in the PCB. High impedance circuits are also

APPLICATIONS INFORMATION

susceptible to electrostatic as well as electromagnetic effects. The static charge carried by a person walking by the circuit can induce an interference on the order of 100's of femtoamps. A metallic shield can reduce this effect as well.

The layout of a high impedance input node is very important. Other signals should be routed well away from this signal path and there should be no internal power planes under it. The best defense from coupling signals is distance and this includes vertically as well as on the surface. In cases where the space is limited, slotting the board around the high impedance input nodes can provide additional isolation and reduce the effect of contamination. In electrically noisy environments the use of driven guard rings around these nodes can be effective (see Figure 8). Adding any additional components such as filters to the high impedance input node can increase leakage. The leakage current of a ceramic capacitor is orders of magnitude larger than the bias current of this device. Any filtering will need to be done after this first stage in the signal chain.

Driving Capacitive Load

The layout of the output node is also very important since LTC6268-10/LTC6269-10 is very sensitive to capacitive loading due to the very high gain-bandwidth-product. Appreciable ringing will be observed when capacitive loading is more than 5pF.

Low Input Offset Voltage

The LTC6268-10 has a maximum offset voltage of $\pm 2.5\text{mV}$ (PNP region) over temperature. The low offset voltage is essential for precision applications. There are 2 different input stages that are used depending on the input common mode voltage. To increase the versatility of the LTC6268-10, the offset voltages are trimmed for both regions of operation.

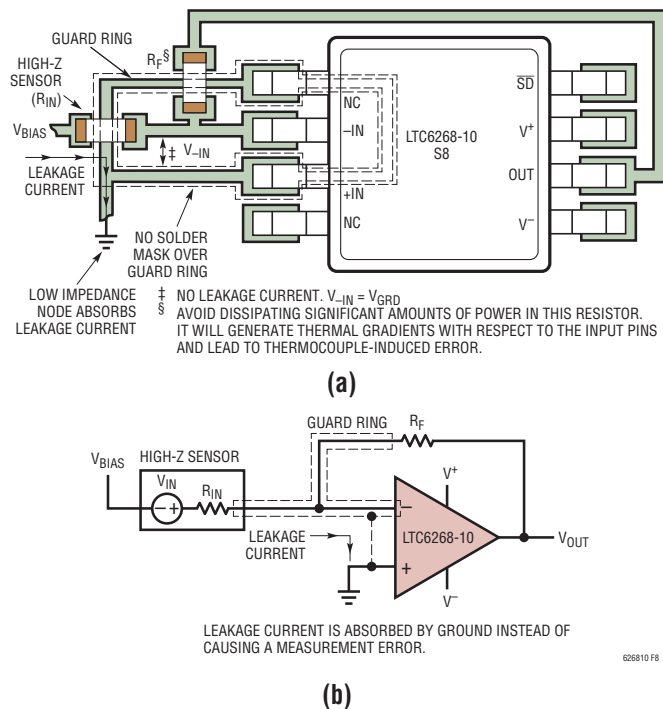

Figure 8. Example Layout of Inverting Amplifier (or Transimpedance) with Leakage Guard Ring

Rail-to-Rail Output

The LTC6268-10 has a rail-to-rail output stage that has excellent output drive capability. It is capable of delivering over $\pm 40\text{mA}$ of output drive current over temperature. Furthermore, the output can reach within 200mV of either rail while driving $\pm 10\text{mA}$. Attention must be paid to keep the junction temperature of the IC below 150°C .

Input Protection

To prevent breakdown of internal devices in the input stage, the two op amp inputs should NOT be separated by more than 2.0V. To help protect the input stage, internal circuitry will engage automatically if the inputs are separated by $> 2.0\text{V}$ and input currents will begin to flow. In all cases, care should be taken so that these currents remain less than 1mA. Additionally, if only one input is driven, internal circuitry will prevent any breakdown condition under

APPLICATIONS INFORMATION

transient conditions. The worst-case differential input voltage usually occurs when the +input is driven and the output is accidentally shorted to ground while in a unity gain configuration.

ESD

ESD Protection devices can be seen in the simplified schematic. The +IN and –IN pins use a sophisticated method of ESD protection that incorporates a total of 4 reverse-biased diodes connected as 2 series diodes to each rail. To maintain extremely low input bias currents, the center node of each of these series diode chains is driven by a buffered copy of the input voltage. This maintains the two diodes connected directly to the input pins at low reverse bias, minimizing leakage current of these ESD diodes to the input pins.

The remaining pins have traditional ESD protection, using reverse-biased ESD diodes connected to each power supply rail. Care should be taken to make sure that the voltages on these pins do not exceed the supply voltages by more than 100mV or these diodes will begin to conduct large amounts of current.

Shutdown

The LTC6268-10S6, LTC6268-10S8, and LTC6268-10DD have $\overline{\text{SHDN}}$ pins that can shut down the amplifier to less than 1.2mA supply current per amplifier. The $\overline{\text{SHDN}}$ pin voltage needs to be within 0.75V of V^- for the amplifier to shut down. During shutdown, the output will be in a high output resistance state, so the LTC6268-10 is suitable for multiplexer applications. The internal circuitry is kept in a low current active state for fast recovery. When left floating, the $\overline{\text{SHDN}}$ pin is internally pulled up to the positive supply and the amplifier is enabled.

PACKAGE DESCRIPTION

Please refer to <http://www.linear.com/designtools/packaging/> for the most recent package drawings.

S6 Package
6-Lead Plastic TSOT-23
 (Reference LTC DWG # 05-08-1636)

NOTE:

1. DIMENSIONS ARE IN MILLIMETERS
2. DRAWING NOT TO SCALE
3. DIMENSIONS ARE INCLUSIVE OF PLATING
4. DIMENSIONS ARE EXCLUSIVE OF MOLD FLASH AND METAL BURR
5. MOLD FLASH SHALL NOT EXCEED 0.254mm
6. JEDEC PACKAGE REFERENCE IS MO-193

S6 TSOT-23 0302

PACKAGE DESCRIPTION

Please refer to <http://www.linear.com/designtools/packaging/> for the most recent package drawings.

S8 Package 8-Lead Plastic Small Outline (Narrow .150 Inch) (Reference LTC DWG # 05-08-1610 Rev G)

PACKAGE DESCRIPTION

Please refer to <http://www.linear.com/designtools/packaging/> for the most recent package drawings.

MS8E Package 8-Lead Plastic MSOP, Exposed Die Pad (Reference LTC DWG # 05-08-1662 Rev K)

NOTE:

1. DIMENSIONS IN MILLIMETER/(INCH)
2. DRAWING NOT TO SCALE
3. DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS.
MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
4. DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS.
INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
5. LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.102mm (.004") MAX
6. EXPOSED PAD DIMENSION DOES INCLUDE MOLD FLASH. MOLD FLASH ON E-PAD SHALL NOT EXCEED 0.254mm (.010") PER SIDE.

PACKAGE DESCRIPTION

Please refer to <http://www.linear.com/designtools/packaging/> for the most recent package drawings.

DD Package
10-Lead Plastic DFN (3mm × 3mm)
 (Reference LTC DWG # 05-08-1699 Rev C)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS

NOTE:

1. DRAWING TO BE MADE A JEDEC PACKAGE OUTLINE M0-229 VARIATION OF (WEED-2).
CHECK THE LTC WEBSITE DATA SHEET FOR CURRENT STATUS OF VARIATION ASSIGNMENT
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE
MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE
TOP AND BOTTOM OF PACKAGE

TYPICAL APPLICATION

100kΩ Gain 90MHz Transimpedance Amplifier

PD = OSI OPTOELECTRONICS, FCI-125G-006
OUTPUT NOISE = 20mVp-p MEASURED ON A 100MHz BW

100kΩ TIA Frequency Response
